

Yes. In an interview, don't explain it with annotations first. **Start with the problem, then explain the solution.** Here's a natural interview answer.

Interview Answer (Simple & Professional)

"In my AI Fitness Recommendation project, I integrated an AI model that generates recommendations, improvements, safety tips, and workout suggestions. Initially, I faced two problems while saving the AI response in MySQL."

Problem 1: Large AI Response

"The AI generated a very detailed recommendation, but my database column was VARCHAR(255). Since the response exceeded 255 characters, MySQL threw the error '**Data too long for column recommendation**'."

Solution:

"I changed the column type from VARCHAR to TEXT using @Lob and @Column(columnDefinition = "TEXT"). This allowed me to store large AI-generated text without truncation."

```
@Lob
```

```
@Column(columnDefinition = "TEXT")
```

```
private String recommendation;
```

Problem 2: Dynamic List Data

"The AI also returned multiple improvements, safety tips, and suggestions as arrays. For example:"

```
[  
  "Increase your pace",  
  "Drink more water"  
]
```

"Initially, I couldn't store this directly in a normal VARCHAR column because it is a list, not a single string."

Solution:

"I used MySQL's JSON data type. In my entity, I added @JdbcTypeCode(SqlTypes.JSON) and @Column(columnDefinition = "json"). Hibernate automatically converts the Java List<String> into JSON while saving and converts it back into a List<String> when fetching the data."

```
@Column(columnDefinition = "json")
```

```
@JdbcTypeCode(SqlTypes.JSON)
```

```
private List<String> improvements;
```
